The first description of psoriasis appears during the Roman Empire in the 1st century AD with books of Celsus. It is in these texts that the limitation of treatment during the middle of the 20th century. The long-term use of arsenic caused toxicity tumors. Its use was widespread until the abandonment of arsenic and boiled viper broth for patients.

Psoriasis is known to be one of the oldest known conditions in medical history. Hippocrates recommended tar and topical arsenic as treatments. St. Hildegard of Bingen advocated the use of salves, lotions, and home remedies to treat the disease.

Psoriasis is a chronic condition that affects an estimated 2–3% of the world’s population. It is characterized by red, scaly patches on the skin, which can be itchy and painful. The disease can affect any part of the body, including the nails and joints.

Psoriasis is thought to be an autoimmune disorder, where the immune system mistakenly attacks healthy skin cells. This can lead to the formation of plaques of skin cells that accumulate on the skin, causing the symptoms of the disease.

Over the centuries, medical treatments for psoriasis have evolved, with some treatments being more effective than others. In recent years, biologic therapies have been developed that target specific proteins involved in the immune response and have shown promising results in treating psoriasis.

Despite the widespread availability of effective treatments, there remains a need for further research to better understand the disease and improve treatment options. This includes understanding the genetic and environmental factors that contribute to the development of psoriasis and developing new treatments that are safe and effective for all patients.
