Rationale for combining basal insulin with a GLP-1 RA

**Glucagon-like peptide-1 receptor agonists (GLP-1 RAs)**

People with type 2 diabetes who do not respond to oral anti-diabetic therapies, which are used to initially control blood glucose levels, may be offered basal insulin injections or treatments such as GLP-1 RAs if their blood glucose levels remain uncontrolled.1

GLP-1 RAs are treatments for type 2 diabetes that mimic a hormone (GLP-1), a type of incretin. Incretins are released in the intestines and stimulate a reduction in blood glucose, which is reflected by measuring the HbA1c in the long term.1 Incretins also slow emptying of the stomach and the flow of nutrients in the body can create the sensation of fullness.

**Importance of preventing complications**

Control of HbA1c is a crucial target in diabetes management. In the United Kingdom (UK), the Quality and Outcomes Framework has set the HbA1c target as 58mmol/mol or less (≤7.5%).² Nearly three quarters of people with type 2 diabetes on basal insulin regimens in the UK fail to reach HbA1c of 58mmol/mol or less (≤7.5%) and are therefore at a greater risk of medical complications.³-⁶

A reduction in HbA1c can provide both a huge personal benefit but also a significant cost saving through the reduction of diabetes-related complications. A one percentage point drop in HbA1c can lead to a 37% reduction in microvascular complications, a 14% reduction in myocardial infarctions and a 21% reduction in overall diabetes-related mortality.⁵
Another challenging complication is hypoglycaemia, which occurs when the concentration of glucose in the blood falls to an abnormally low level. Episodes can have a significant impact on a person living with diabetes as symptoms can range from trembling, sweating, poor sleep and nightmares to night-time convulsions and, in severe cases, coma and death.

Insulin is an effective diabetes treatment, but it is often underutilised due to the risk or fear of hypoglycaemia - and also possible weight gain. These two factors can be a major barrier to insulin initiation and optimising the use of insulin.

Benefits for combining basal insulin with GLP-1 RA

There may be important benefits associated with using basal insulin with a GLP-1 RA:
- Improvements in blood glucose levels overall
- A lower risk of hypoglycaemia compared to taking a higher dose of insulin
- Using basal insulin and a GLP-1 RA together may lower insulin-associated weight gain and may achieve weight loss
