

Understanding Mantle Cell Lymphoma (MCL)

Lymphoma is a blood cancer caused by the rapid production of lymphocytes, a type of white blood cell.¹ B-cells and T-cells are the two types of lymphocytes that can develop into lymphomas.²

The two main types of lymphoma are Hodgkin lymphoma and non-Hodgkin lymphoma (NHL).¹

MCL is a rare, aggressive or indolent NHL, typically resulting from a malignant transformation of a B-cell in the outer edge of a lymph node (mantle zone).^{3,4}

Disease Burden

MCL represents **approximately 3% of all NHL cases in the US.**⁵

The **average age of diagnosis is the mid-60s.**⁶

Men are more likely to have MCL than women.⁶

MCL is often diagnosed as a late-stage disease that has spread to the gastrointestinal tract and bone marrow.³

The Unmet Medical Need

There is no cure for MCL; however, there are treatment options to help manage the disease.⁷

Recent treatment advances have improved patient outcomes. Unfortunately, **for many patients the disease may return after treatment.**⁶

Additional treatment options are needed for people who relapse or do not respond to treatment.
